ACID : Atomicity: Data is written or read by all the transactions in a consistent state. Consistency: All data is safe and not dirty. Isolation: Apparent failures of any component don't corrupt the result. Dependability: If a component quits, transactions still complete and commit successfully. Durability: Data remains on disk with no corruption or data loss. It's purely dependent on the application not on the database itself (the database can have an issue). So you can use auto-commit in your application and be safe. Also some of the newer databases like MS SQL Server allows the use of "snapshot isolation" which is also a way to get ACID. A: A bus error happens when you try to access memory you're not supposed to. This may be the case with your database tables, indexes or even queries. There can be any number of underlying reasons for a bus error. Do you have an application that's trying to update a column in a table with a NULL value? Is your database corrupted? A: This bus error f678ea9f9e
